

AI ASSISTED CODING

SHASHANK YELAGAM

2303A51013

BATCH – 03

30 – 01 – 2026

ASSIGNMENT – 5.5

Lab 5: Ethical Foundations – Responsible AI Coding Practices.

TASK - 01: (Transparency in Algorithm Optimization)

Prompt: Generate Python code for two prime-checking methods and explain how the optimized version improves performance.

Code:

1. Basic Prime Checking Function

The screenshot shows a Jupyter Notebook interface with the following code in a cell:

```
[1]: def is_prime_basic(n):
    """Checks if a number is prime using a basic approach."""
    if n < 2:
        return False
    for i in range(2, n):
        if n % i == 0:
            return False
    return True

# Test the basic function
print("Is 17 prime (basic)?", is_prime_basic(17))
print("Is 20 prime (basic)?", is_prime_basic(20))
print("Is 2 prime (basic)?", is_prime_basic(2))
print("Is 1 prime (basic)?", is_prime_basic(1))
```

The output of the code is displayed below the cell:

```
... Is 17 prime (basic)? True
Is 20 prime (basic)? False
Is 2 prime (basic)? True
Is 1 prime (basic)? False
```

The interface includes a toolbar at the top with icons for Commands, Code, Text, Run all, RAM, and Disk. At the bottom, there are tabs for Variables, Terminal, and Python 3, along with a status bar showing the time as 11:07 AM.

2. Optimized Prime Checking Function

The screenshot shows a Jupyter Notebook interface with the following code in a cell:

```
import math

def is_prime_optimized(n):
    """Checks if a number is prime using an optimized approach."""
    if n < 2:
        return False
    if n == 2 or n == 3:
        return True
    if n % 2 == 0 or n % 3 == 0:
        return False

    # Check for factors from 5 up to the square root of n
    # Only need to check numbers of the form 6k +/- 1
    i = 5
    while i * i <= n:
        if n % i == 0 or n % (i + 2) == 0:
            return False
        i += 6
    return True

# Test the optimized function
print(f"Is 17 prime (optimized)? {is_prime_optimized(17)}")
print(f"Is 20 prime (optimized)? {is_prime_optimized(20)}")
print(f"Is 2 prime (optimized)? {is_prime_optimized(2)}")
print(f"Is 1 prime (optimized)? {is_prime_optimized(1)}")
print(f"Is 97 prime (optimized)? {is_prime_optimized(97)}")
```

Below the code cell, the status bar shows "Variables" and "Terminal". At the bottom right, it says "11:07 AM" and "Python 3".

Transparent Explanation:

Naive Method Time Complexity: $O(n)$ → Checks all numbers from 2 to $n-1$.

Optimized Method Time Complexity: $O(\sqrt{n})$ → Only checks up to square root of n .

Comparison :

| Method | Time Complexity | Performance |
|-----------|-----------------|-------------|
| Naive | $O(n)$ | Slower |
| Optimized | $O(\sqrt{n})$ | Faster |

Task – 02 : Transparency in Recursive Algorithms.

Prompt : Give me the Recursive Fibonacci code with clear comments.

Code:

The screenshot shows a Jupyter Notebook interface. The code cell contains a recursive Fibonacci function. The output cell shows the result of calling the function with num=10, which prints "The 10th Fibonacci number is: 55". The notebook has tabs for Commands, Code, Text, Run all, RAM, Disk, and a toolbar with various icons.

```
[5] def fibonacci(n):
    # Base case: if n is 0, return 0
    if n == 0:
        return 0

    # Base case: if n is 1, return 1
    if n == 1:
        return 1

    # Recursive case: sum of previous two Fibonacci numbers
    return fibonacci(n-1) + fibonacci(n-2)

# Example usage: calculate the 10th Fibonacci number
num = 10
print(f"The {num}th Fibonacci number is: {fibonacci(num)}")
```

... The 10th Fibonacci number is: 55

Explanation:

- Base Cases:
 - $\text{fibonacci}(0) \rightarrow 0$ $\text{fibonacci}(1) \rightarrow 1$
- Recursive Call:
 - $\text{fibonacci}(n) = \text{fibonacci}(n-1) + \text{fibonacci}(n-2)$

Task – 03 : Transparency in Error Handling.

Prompt: Generate code with proper error handling and clear explanations for each exception.

Code:

```
[1]: def fibonacci(n):
    # Input validation
    if not isinstance(n, int):
        raise TypeError("Input must be an integer.")
    if n < 0:
        raise ValueError("Input cannot be a negative number.")

    # Base case: if n is 0, return 0
    if n == 0:
        return 0

    # Base case: if n is 1, return 1
    if n == 1:
        return 1

    # Recursive case: sum of previous two Fibonacci numbers
    return fibonacci(n-1) + fibonacci(n-2)

# Example usage with error handling:

# Test with valid input
try:
    num = 10
    print(f"The {num}th Fibonacci number is: {fibonacci(num)}")

```

Variables Terminal 11:22 AM Python 3

```
[1]: print(f"The {num}th Fibonacci number is: {fibonacci(num)}")
except (TypeError, ValueError) as e:
    print(f"Error for input {num}: {e}")

# Test with negative input
try:
    num = -5
    print(f"The {num}th Fibonacci number is: {fibonacci(num)}")
except (TypeError, ValueError) as e:
    print(f"Error for input {num}: {e}")

# Test with non-integer input
try:
    num = 5.5
    print(f"The {num}th Fibonacci number is: {fibonacci(num)}")
except (TypeError, ValueError) as e:
    print(f"Error for input {num}: {e}")

# Test with string input
try:
    num = "abc"
    print(f"The {num}th Fibonacci number is: {fibonacci(num)}")
except (TypeError, ValueError) as e:
    print(f"Error for input '{num}': {e}")

```

Variables Terminal 11:22 AM Python 3

Explaining the Errors:

| Exception | Meaning |
|-------------------------|--|
| FileNotFoundException | File does not exist |
| PermissionError | No permission to read file |
| Any other unknown error | <u>Task – 04 : Security in User Authentication.</u> Code: |

Insecure Version:

```
[11] In [Os]
users = {}

def register_user(username, password):
    """Registers a new user with the provided username and password."""
    users[username] = password
    print(f"User '{username}' registered successfully.")

def login_user(username, password):
    """Authenticates a user based on username and password."""
    if username in users and users[username] == password:
        print(f"Login successful for user '{username}'")
        return True
    else:
        print(f"Login failed for user '{username}'. Invalid credentials.")
        return False

# Demonstrate functionality
print("\n--- Demonstrating User Registration and Login ---")

# 1. Register a user
register_user("alice", "password123")
register_user("bob", "secure_pass")

# 2. Attempt to log in with correct credentials
login_user("alice", "password123")

# 3. Attempt to log in with incorrect password
login_user("alice", "wrong_password")

# 4. Attempt to log in with non-existent username
login_user("charlie", "anypass")

print("\nCurrent registered users and their passwords (for demonstration purposes):")
print(users)
```

The code defines two functions: `register_user` and `login_user`. It uses a global dictionary `users` to store user credentials. The `register_user` function adds a new user to the dictionary. The `login_user` function checks if the provided username and password match those in the dictionary. The code then demonstrates these functions by registering two users ('alice' and 'bob') and attempting to log in with various credentials.

Secure Version:

```
[10] In [26]
import bcrypt
import re # Import regex for advanced input validation

hashed_users = {}

def register_user_secure(username, password):
    """Registers a new user with a securely hashed password and robust input validation."""
    # Strip whitespace from username and password
    username = username.strip()
    password = password.strip()

    # 1. Basic validation for emptiness
    if not username or not password:
        print("Username and password cannot be empty or just whitespace.")
        return False

    # 2. Username validation: alphanumeric and allowed symbols (-, _, .)
    if not re.fullmatch("[a-zA-Z0-9_.-]", username):
        print("Username can only contain alphanumeric characters, '.', '_', or '-'")
        return False

    if len(username) < 3:
        print("Username must be at least 3 characters long.")
        return False

    # 3. Check for existing username
    if username in hashed_users:
        print(f"Username '{username}' already exists. Please choose a different one.")
        return False

    # 4. Password complexity requirements
    if len(password) < 8:
        print("Password must be at least 8 characters long.")
        return False

    if not re.search("[A-Z]", password):
        print("Password must contain at least one uppercase letter 'A-Z'.")
```

This version of the code uses `bcrypt` for password hashing and `re` for regular expression validation. It performs more stringent validation than the insecure version, including checking for specific character sets and lengths, and ensuring uniqueness of the username. It also handles edge cases like empty strings and whitespace.

```

# Hash the password using bcrypt
hashed_password = bcrypt.hashpw(password.encode('utf-8'), bcrypt.gensalt())
hashed_users[username] = hashed_password
print(f"User '{username}' registered securely.")

def login_user_secure(username, password):
    """Authenticates a user against their securely hashed password with input stripping."""
    # Strip whitespace from username and password
    username = username.strip()
    password = password.strip()

    if username not in hashed_users:
        print("Login failed: Invalid credentials.") # Generic message for security
        return False

    # Check the provided password against the stored hash
    if bcrypt.checkpw(password.encode('utf-8'), hashed_users[username]):
        print(f"Login successful for user '{username}'.")
        return True
    else:
        print("Login failed: Invalid credentials.") # Generic message for security
        return False

# Demonstrate functionality with enhanced secure system
print("\n--- Demonstrating Enhanced Secure User Registration and Login ---")

# 1. Register users with new validations
register_user_secure("jane_doe", "StrongPass1!")
register_user_secure("user_with_space", "ValidPass20") # Invalid username
register_user_secure("anotheruser", "ValidPass20") # Invalid username
register_user_secure("bob", "weak") # Password too short
register_user_secure("carl", "onlylowercase") # Missing uppercase, digit, special
register_user_secure("david", "SecurePass4") # Missing special character
register_user_secure("emily", "emily123!") # Valid password, but username exists
register_user_secure("emily", "Emilly!P4ss") # Valid registration

# 2. Demonstrate stripping whitespace
register_user_secure(" padded_user ", " PaddedPass5$ ") # Should register 'padded_user'
login_user_secure("padded_user", "PaddedPass5$")
login_user_secure(" padded_user ", "PaddedPass5$") # Login with padded username
login_user_secure("padded_user", " PaddedPass5$ ") # Login with padded password

# 3. Attempt to log in with correct credentials
login_user_secure("jane_doe", "StrongPass1!")

# 4. Attempt to log in with incorrect password
login_user_secure("jane_doe", "wrong_password")

# 5. Attempt to log in with non-existent username
login_user_secure("frank", "anypass")

print("\nCurrent registered users (hashed passwords stored, not displayed for security):")
print(f"Users registered: {list(hashed_users.keys())}")

...
--- Demonstrating Enhanced Secure User Registration and Login ---
User 'jane_doe' registered securely.
Username can only contain alphanumeric characters, '.', '_', or '-'.
Username can only contain alphanumeric characters, '.', '_', or '-'.
Password must be at least 8 characters long.
Password must contain at least one uppercase letter.

```

This screenshot shows a Python code editor with a script demonstrating enhanced secure user registration and login. The script includes password hashing, input stripping, and various validation cases. It also shows how to handle registered users and logins.

```

# 1. Register users with new validations
register_user_secure("jane_doe", "StrongPass1!")
register_user_secure("user-with-space", "ValidPass20") # Invalid username
register_user_secure("anotheruser", "ValidPass20") # Invalid username
register_user_secure("bob", "weak") # Password too short
register_user_secure("carl", "onlylowercase") # Missing uppercase, digit, special
register_user_secure("david", "SecurePass4") # Missing special character
register_user_secure("emily", "emily123!") # Valid password, but username exists
register_user_secure("emily", "Emilly!P4ss") # Valid registration

# 2. Demonstrate stripping whitespace
register_user_secure(" padded_user ", " PaddedPass5$ ") # Should register 'padded_user'
login_user_secure("padded_user", "PaddedPass5$")
login_user_secure(" padded_user ", "PaddedPass5$") # Login with padded username
login_user_secure("padded_user", " PaddedPass5$ ") # Login with padded password

# 3. Attempt to log in with correct credentials
login_user_secure("jane_doe", "StrongPass1!")

# 4. Attempt to log in with incorrect password
login_user_secure("jane_doe", "wrong_password")

# 5. Attempt to log in with non-existent username
login_user_secure("frank", "anypass")

print("\nCurrent registered users (hashed passwords stored, not displayed for security):")
print(f"Users registered: {list(hashed_users.keys())}")

...
--- Demonstrating Enhanced Secure User Registration and Login ---
User 'jane_doe' registered securely.
Username can only contain alphanumeric characters, '.', '_', or '-'.
Username can only contain alphanumeric characters, '.', '_', or '-'.
Password must be at least 8 characters long.
Password must contain at least one uppercase letter.

```

This screenshot shows a Python code editor with a script demonstrating enhanced secure user registration and login. The script includes password hashing, input stripping, and various validation cases. It also shows how to handle registered users and logins.

Explanation :

- ✓ Always hash passwords
- ✓ Never store plain-text passwords
- ✓ Validate user input
- ✓ Use strong hashing algorithms

Task – 05 : Privacy in Data Logging.

Prompt – 01 : Create a basic Python script that simulates logging user activity, including username, IP address, and timestamp, to a file or console.

Code:

Privacy and Risky Logging:

The screenshot shows a Python code editor interface with the following details:

- Title Bar:** Shows tabs for "Commands", "Code", "Text", "Run all", and "RAM/Disk status".
- Code Area:** Contains a Python script named "log_user_activity.py".

```
[14] ✓ Os
import datetime

def log_user_activity(username, ip_address):
    """Logs user activity including username, IP address, and timestamp to a file."""
    timestamp = datetime.datetime.now().strftime("%Y-%m-%d %H:%M:%S")
    log_message = f"[{timestamp}] User: {username}, IP: {ip_address}, Action: Logged In"

    try:
        with open("user_activity.log", "a") as f:
            f.write(log_message + "\n")
            print(f"Logged: {log_message}")
    except Exception as e:
        print(f"Error writing to log file: {e}")

# Simulate logging user activity
print("--- Simulating User Activity Logging ---")
log_user_activity("alice", "192.168.1.100")
log_user_activity("bob", "10.0.0.5")
log_user_activity("alice", "192.168.1.100") # Another action from Alice
log_user_activity("charlie", "172.16.0.25")

print("\nCheck 'user_activity.log' file for logs.")
```
- Bottom Status Bar:** Shows "Variables", "Terminal", a blue play button icon, "11:46 AM", and "Python 3".

Prompt - 02 : Examine the initial logging script to identify specific privacy risks associated with logging sensitive data like usernames and IP addresses directly. Detail potential negative impacts.

Code:

The screenshot shows a Python code editor interface with the following details:

- Title Bar:** Shows tabs for "Commands", "Code", "Text", "Run all", and "RAM/Disk status".
- Code Area:** Contains a Python script named "log_user_activity_private.py".

```
[15] ✓ Os
import datetime
import hashlib

def log_user_activity_private(username, ip_address):
    """Logs user activity with privacy-aware practices (hashed username, masked IP)."""

    # 3. Generate a timestamp
    timestamp = datetime.datetime.now().strftime("%Y-%m-%d %H:%M:%S")

    # 4. Hash the username using SHA256
    hashed_username = hashlib.sha256(username.encode()).hexdigest()

    # 5. Mask the ip_address by replacing the last octet with 'XXX'
    ip_parts = ip_address.split('.')
    if len(ip_parts) == 4:
        masked_ip_address = ".".join(ip_parts[:-1]) + ".XXX"
    else:
        masked_ip_address = "UNKNOWN_IP"

    # 6. Construct a log message
    log_message = f"[{timestamp}] User_Hash: {hashed_username}, IP_Masked: {masked_ip_address}, Action: Logged In"

    # 7. Write this log message to a new file
    ...
```
- Bottom Status Bar:** Shows "Variables", "Terminal", a blue play button icon, "11:46 AM", and "Python 3".

The screenshot shows a Jupyter Notebook interface. The code cell contains Python code for logging user activity. The terminal output shows simulated privacy-enhanced user activity logs.

```
# 7. Write this log message to a new file
try:
    with open("user_activity_private.log", "a") as f:
        f.write(log_message + "\n")
        print(f"Logged (Private): {log_message}")
except Exception as e:
    print(f"Error writing to private log file: {e}")

# 8. Call the log_user_activity_private function with several example usernames and IP addresses
print("\n--- Simulating Privacy-Enhanced User Activity Logging ---")
log_user_activity_private("alice", "192.168.1.100")
log_user_activity_private("bob", "10.0.0.5")
log_user_activity_private("alice", "192.168.1.100") # Another action from Alice
log_user_activity_private("charlie", "172.16.0.25")
log_user_activity_private("diana", "203.0.113.42")

print("\nCheck 'user_activity_private.log' file for privacy-enhanced logs.")

...
--- Simulating Privacy-Enhanced User Activity Logging ---
Logged (Private): [2026-01-30 06:16:19] User_Hash: 2bd806c97f0e00af1a1fc3328fa763a9269723c8db8fac4f93af71db186d6e90, IP_Masked: 192.168.1.XXX, Action: Logged (Private): [2026-01-30 06:16:19] User_Hash: 81b637d8fcfd2c6da6359e6963113a1170de795e4b725b84d1a0b4cf9ec58ce9, IP_Masked: 10.0.0.XXX, Action: Logged (Private): [2026-01-30 06:16:19] User_Hash: 2bd806c97f0e00af1a1fc3328fa763a9269723c8db8fa4f93af71db186d6e90, IP_Masked: 192.168.1.XXX, Action: Logged (Private): [2026-01-30 06:16:19] User_Hash: b9dd960c1753459a78115d3cb845a57d924b6877e805b08bd01086ccdf34433c, IP_Masked: 172.16.0.XXX, Action:
```

Explanation:

- ✓ Mask or anonymize sensitive data
- ✓ Log only what is necessary
- ✓ Avoid storing personal identifiers
- ✓ Protect log files from unauthorized access

THANK YOU!!
